

# The Mu2e Experiment at Fermilab

Fabio Happacher, LNF-INFN  
On behalf of the Mu2e Collaboration

**WONP-2019 - XVII Workshop on Nuclear Physics**

La Habana – April 1- 5, 2019

# Presentation outline

---

- Where, Why Muon 2 Electron conversion
- How, the experimental technique
- Accelerator complex
- Detectors layout, indulging on the Calorimeter
- Status of Mu2e construction
- Conclusions

# The Mu2e collaboration @FNAL muon campus

## ~230 Scientists from 37 Institutions

Argonne National Laboratory, Boston University, Brookhaven National Laboratory, University of California Berkeley, University of California Irvine, California Institute of Technology, City University of New York, **Joint Institute of Nuclear Research Dubna**, Duke University, Fermi National Accelerator Laboratory, **Laboratori Nazionali di Frascati**, University of Houston, **Helmholtz-Zentrum Dresden-Rossendorf**, University of Illinois, **INFN Genova**, Lawrence Berkeley National Laboratory, **INFN Lecce**, **University Marconi Rome**, **Institute for High Energy Physics Protvino**, Kansas State University, Lewis University, **University of Liverpool**, **University College London**, University of Louisville, **University of Manchester**, University of Minnesota, Muons Inc., Northwestern University, Institute for Nuclear Research Moscow, Northern Illinois University, **INFN Pisa**, Purdue University, Novosibirsk State University/Budker Institute of Nuclear Physics, Rice University, University of South Alabama, University of Virginia, University of Washington, Yale University

# Intro

## The Periodic Table of Elementary Particles and Forces

- We've known for a long time that quarks mix via  $W \rightarrow$  (Quark) Flavor Violation
  - Mixing strengths parameterized by Cabbibo-Kobayashi-Maskawa - CKM matrix
- In last 15 years we learned that neutrinos mix  $\rightarrow$  Lepton Flavor Violation (LFV)
  - Mixing strengths parameterized by Pontecorvo-Maki-Nakagawa-Sakata - PMNS matrix
- Why not charged leptons?
  - Charged Lepton Flavor Violation (CLFV)

Three Generations of Matter (Fermions)

# Why a Search for $\mu^- N \rightarrow e^- N$ ?

- Mu2e searches for **muon-to-electron conversion** in the coulomb field of a nucleus
- CLFV processes are **strongly suppressed in the Standard Model**
  - it is not forbidden due to neutrino oscillations
  - In practice  $\text{BR}(\mu \rightarrow e \gamma) \sim \Delta m_\nu^2 / M_W^2 < 10^{-54}$   
thus not observable
- **BSM Physics could enhance CLFV rates** to observable values
- Muon-to-electron conversion is similar but complementary to other CLFV processes as  $\mu \rightarrow e \gamma$  and  $\mu \rightarrow 3e$ .
- **A detected signal would be evidence of physics beyond the SM (BSM)** -  
Susy, Compositeness, Leptoquark, Heavy neutrinos, Second Higgs Doublet, Heavy  $Z'$

# Some CLFV Processes

Process	Current Limit	Next Generation exp
$\tau \rightarrow \mu\eta$	BR < 6.5 E-8	$10^{-9} - 10^{-10}$ (Belle II)
$\tau \rightarrow \mu\gamma$	BR < 6.8 E-8	
$\tau \rightarrow \mu\mu\mu$	BR < 3.2 E-8	
$\tau \rightarrow eee$	BR < 3.6 E-8	
$K_L \rightarrow e\mu$	BR < 4.7 E-12	
$K^+ \rightarrow \pi^+ e^- \mu^+$	BR < 1.3 E-11	
$B^0 \rightarrow e\mu$	BR < 7.8 E-8	
$B^+ \rightarrow K^+ e\mu$	BR < 9.1 E-8	$10^{-14}$ (MEG)
$\mu^+ \rightarrow e^+ \gamma$	BR < 4.2 E-13	
$\mu^+ \rightarrow e^+ e^+ e^-$	BR < 1.0 E-12	
$\mu N \rightarrow e N$	$R_{\mu e} < 7.0 \text{ E-13}$	
		$10^{-16}$ (PSI)
		$10^{-17}$ (Mu2e, COMET)

- There is a global interest in CLFV
- Most promising CLFV measurements use  $\mu$
- in most BSM models CLFV effects are present at rates that some next generation experiments will be sensitive to

# $\mu \rightarrow e$ is a signature of BSM models

Loop terms

## Heavy Neutrinos

$$|U_{\mu N} U_{eN}|^2 \sim 8 \times 10^{-13}$$

## Second Higgs Doublet

$$g(H_{\mu e}) \sim 10^{-4} g(H_{\mu\mu})$$

## Supersymmetry

$$\text{rate} \sim 10^{-15}$$

Models which can be probed also by  $\mu \rightarrow e \gamma$  searches

Contact terms

## Heavy $Z'$ Anomal. Z Coupling

$$M_{Z'} = 3000 \text{ TeV}/c^2$$

## Compositeness

$$\Lambda_c \sim 3000 \text{ TeV}$$

## Leptoquark

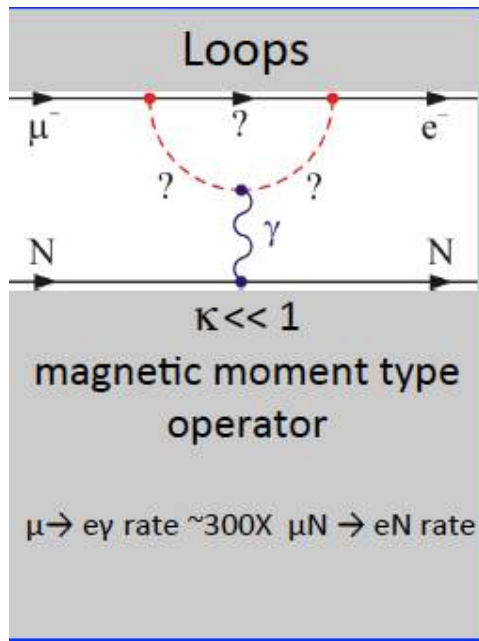

$$M_{LQ} = 3000 (\lambda_{\mu d} \lambda_{e d})^{1/2} \text{ TeV}/c^2$$

Direct coupling between quarks and leptons, better accessed by  $\mu N \rightarrow e N$

# Mu2e Sensitivity

$$\mathcal{L}_{\text{CLFV}} = \frac{m_\mu}{(1 + \kappa) \Lambda^2} \bar{\mu}_R \sigma_{\mu\nu} e_L F^{\mu\nu} + \frac{\kappa}{(1 + \kappa) \Lambda^2} \bar{\mu}_L \gamma_\mu e_L (\bar{u}_L \gamma^\mu u_L + \bar{d}_L \gamma^\mu d_L)$$

Mu2e Sensitivity best in all scenarios

# What is Mu2e

- Will search the conversion of a muon into an electron after stopping it

This is what we start with.

This is the process we are looking for.

- Will use current the intense proton beam of the Fermilab accelerator complex to reach a single event sensitivity of  $\sim 2.5 \times 10^{-17}$  i.e.  $10^4$  better than current world's best (Sindrum II)
- Will have *discovery* sensitivity over broad swath of BSM Physics parameter space
- Mu2e will detect and count the electrons coming from the conversion decay of a muon with respect to standard muon capture

$$R_{\mu e} = \frac{\Gamma(\mu^- + (A, Z) \rightarrow e^- + (A, Z))}{\Gamma(\mu^- + (A, Z) \rightarrow \nu_\mu + (A, Z-1))}$$

# As low probability as this!

---

# Mu2e operating principle

---

- Generate a intense beam ( $10^{10}/s$ ) of low momentum ( $p_T < 100$  MeV/c) negative  $\mu$ 's
- $p + \text{nucleus} \rightarrow \pi^- \rightarrow \mu^- \nu_\mu$
- Every 1 second Mu2e will
  - Send 7,000,000,000,000 protons to the Production Solenoid
  - Send 26,000,000,000  $\mu$ s through the Transport Solenoid
  - Stop 13,000,000,000,  $\mu$ s in the Detector Solenoid
- Stop the muons in Al target
  - Sensitivity goal requires  $\sim 10^{18}$  stopped muons
  - $10^{20}$  protons on target (2 year run -  $2 \times 10^7$  s)
- The stopped muons are trapped in orbit 1S around the nucleus
  - In aluminum:  $\tau_\mu^{\text{Al}} = 864$  ns
  - Large  $\tau_\mu^{\text{N}}$  important for reducing background
- Look for events consistent with  $\mu N \rightarrow e N$

# Some Perspective

---

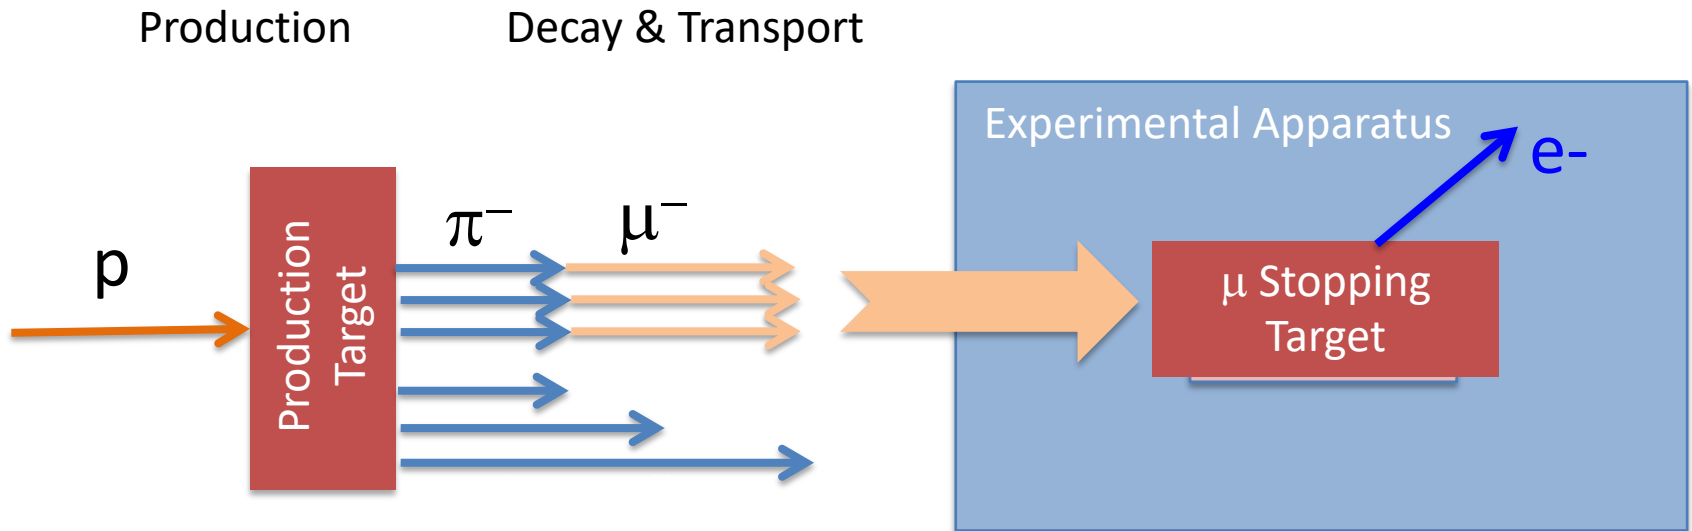

1,000,000,000,000,000,000

= number of stopped Mu2e muons

= number of grains of sand on earth's beaches

# Mu2e Concept in a sketch

From the cartoons .... To real tough life

# Mu2e Experimental Apparatus

- Derived from MELC concept originated by Lobashev and Djilkibaev in 1989

# Using Solenoids to Collect Muons

Compare to  $\vec{B} = 0$

- SINDRUM-II used  $\sim 1$  MW beam to produce  $\sim 10^{7-8}$  stopped  $\mu/s$

## Mu2e muon collection

Proton target in solenoidal  $\vec{B}$  field

- Soft pions confined: collect most of resulting muons

- Solenoids enable us to collect  $\sim 10^{10}$   $\mu/s$  using an 8kW beam.

# Muonic Al atom

---

Before going to the experimental setup, let's see the topology of the events we are dealing with.

- Low momentum  $\mu^-$  is captured in atomic orbit
  - Quickly ( $\sim$ fs) cascades to 1s state emitting X-rays
- Bohr radius  $\sim 20$  fm (for aluminum)
  - Significant overlap of  $\mu^-$  and Nucleus wave functions
- Once in 1s state, 3 main process (might) take place
  - Conversion :  $\mu^-N_{(A,Z)} \rightarrow e^-N_{(A,Z)}$  (signal)
  - Muon Capture :  $\mu^-N_{(A,Z)} \rightarrow \nu N^*_{(A,Z-1)}$  (61%) (normalization)
  - Decay :  $\mu^-N_{(A,Z)} \rightarrow e^-\nu\nu N_{(A,Z)}$  (39%) (main bkg)

# Mu2e Measurement factors

$$R_{\mu e} = \frac{\Gamma(\mu^- + (A, Z) \rightarrow e^- + (A, Z))}{\Gamma(\mu^- + (A, Z) \rightarrow \nu_\mu + (A, Z-1))}$$

- Muon is trapped on Aluminum

and...

# The numerator, i.e. **the signal**

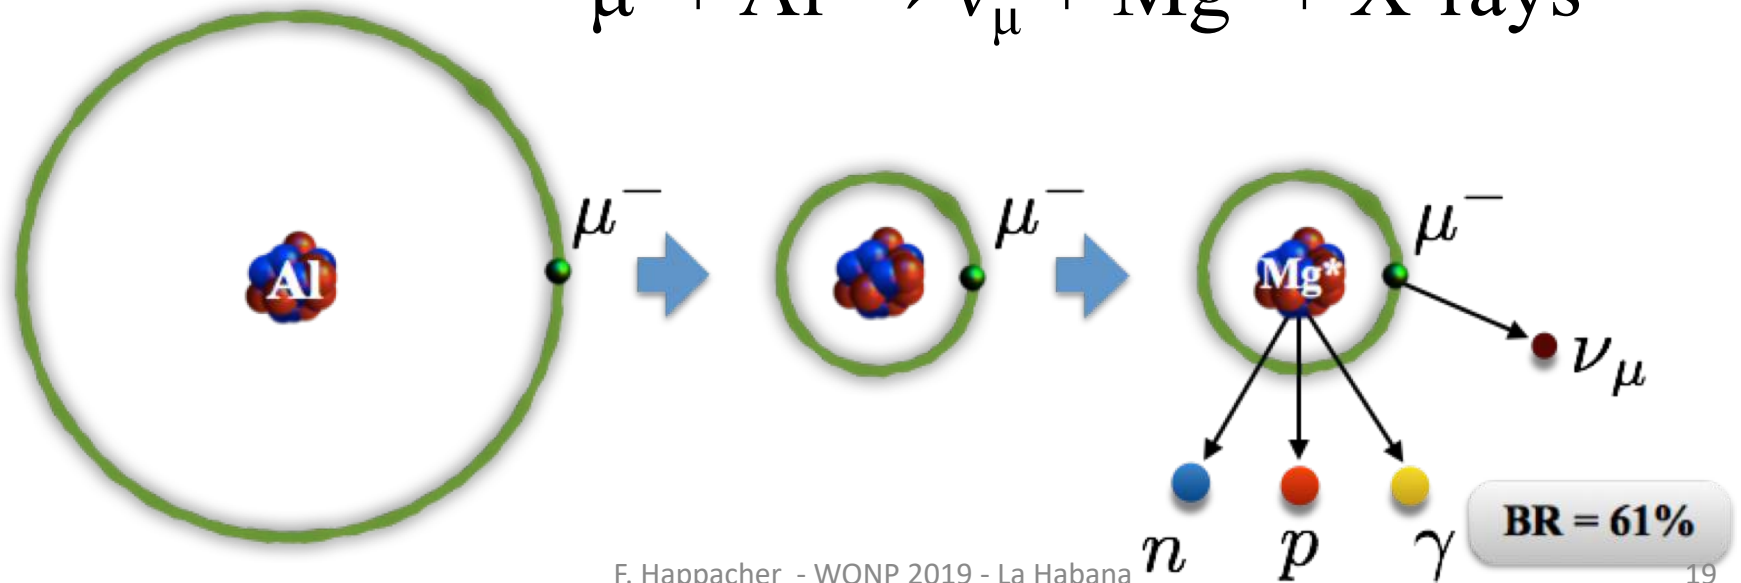

...neutrinoless converts to a monoenergetic electron.

**or..**

# The denominator, i.e. **the normalization**

...61 % of the time, interacts with the Aluminum nucleus to form Magnesium. We know well the X ray emissions of capture processes and relative rates: we measure their rate and know how many muons have been stopped

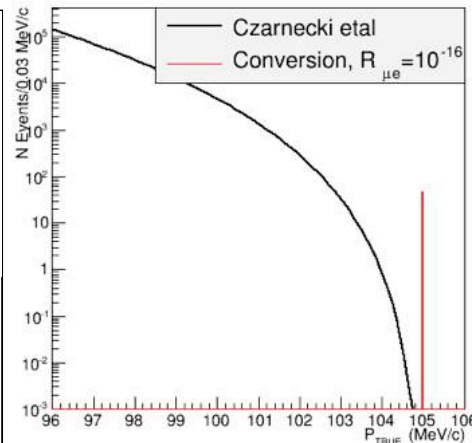

# Mu2e intrinsic backgrounds

Unfortunately, 39 % of the time, muons can also:

Weak Decay in orbit (DIO):  $[\mu^- + A(N, Z)]_{bound}^{1S} \rightarrow A(N, Z) + e^- + \bar{\nu}_e + \nu_\mu$

- The Michel spectrum is distorted by the presence of the nucleus
- If the neutrinos are at rest the  $e^-$  can have exactly the conversion energy  $E_{CE}=104.97$  MeV, contaminating the signal region
- Electron spectrum has tail out to 104.96 MeV
- Accounts for ~55% of total background

**Drives exp. resolution**

Separation of ~few 100 keV for  $R_{\mu e} = 10^{-16}$

# Decay in orbit

Decay In Orbit (DIO) ~ 39%

Mu2e Intrinsic Background

# Backgrounds to deal with

Stopped  $\mu^-$ 's

- Muon decay in orbit (DIO)
- Radiative muon capture (RMC)

Late protons

- Pions from late protons can undergo radiative capture (RPC) ( $\tau_{\pi}^{\text{Al}} = 26 \text{ ns}$ )

$\gamma$  energy up to  $m_{\pi}$ , peak at 110 KeV. One electron can mimic signal

- Pions/muons decay in flight
- Antiprotons produce pions when they annihilate in the target: are negative and they can be slow
- Electrons from beam
- Cosmic rays

The atomic, nuclear, and particle physics of  $\mu^-$  drive the design of the experiment

# prompt vs late arriving bkg

Category	Background Process	Estimated Yield
Intrinsic	Decay In Orbit (DIO)	$0.144 \pm 0.028(\text{stat}) \pm 0.11(\text{syst})$
	Muon Capture (RMC)	0
Late Arriving	Pion Capture (RPC)	$0.021 \pm 0.001(\text{stat}) \pm 0.002(\text{syst})$
	Muon Decay in Flight	$< 0.003$
	Pion Decay in Flight	$0.001 \pm <0.001$
	Beam Electrons	$(2.1 \pm 1.0) \times 10^{-4}$
Miscellaneous	Cosmic Ray Induced	$0.209 \pm 0.022(\text{stat}) \pm 0.055(\text{syst})$
	Antiproton Induced	$0.040 \pm 0.001(\text{stat}) \pm 0.020(\text{syst})$
<b><u>Total</u></b>		<b><u><math>0.41 \pm 0.13(\text{stat} + \text{syst})</math></u></b>

Prompt background, like radiative pion capture, decreases rapidly ( $\sim 10^{11}$  reduction after 700 ns). RPC was limiting Sindrum II current limit. Mu2e scheme is capable to keep it under control.

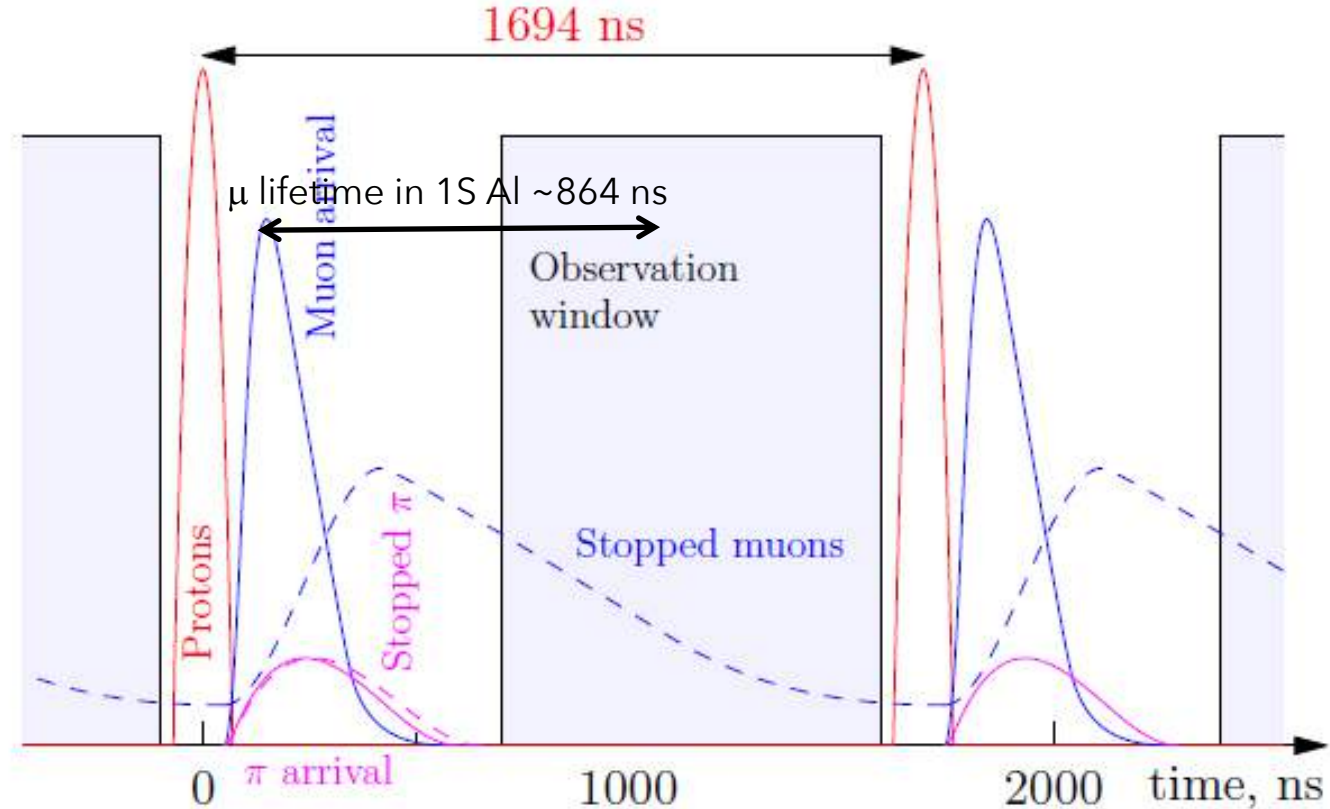

# Accelerator & proton extinction

- Mu2e will repurpose much of the Tevatron anti-proton complex to instead produce muons.
- Booster: 21 batches of  $4 \times 10^{12}$  of 8 GeV protons every  $1/15^{\text{th}}$  second
- Booster “batch” is injected into the Recycler ring and re-bunched into 4 smaller bunches
- These are extracted one at a time to the Delivery ring
- As a bunch circulates, protons are extracted to produce the desired beam structure → pulses of  $\sim 3 \times 10^7$  protons each, separated by  $1.7 \mu\text{s}$
- **Proton Extinction** between bunches
  - $(N_p \text{ out of bunch}) / (N_p \text{ in bunch})$
  - Internal: momentum scraping and bunch formation
  - External: oscillating AC dipole

Accelerator models show that this combination ensures  $\sim 10^{-12}$

# Pulsed beam structure

- Use the fact that muonic atomic lifetime  $\gg$  prompt background  
Need a pulsed beam to wait for prompt background to reach acceptable levels  
→ Fermilab accelerator complex provides ideal pulse spacing  
a 700 ns delay reduces pion background by  $>10^{-9}$
- Out of time protons are also a problem  $\rightarrow$  prompt bkg arriving late  
To keep background low we need proton extinction  $<10^{-10}$

# The Mu2e beamline

- Mu2e Solenoid System
  - Superconducting
    - Requires a cryogenic system
  - Inner bore evacuated to  $10^{-4}$  Torr to limit background due to interactions of the charged particles with air

# Signal event in the apparatus

---

Production  
Solenoid

Transport  
Solenoid

Detector  
Solenoid

# The Mu2e beamline

## • Production Solenoid

- Pulsed proton beam coming from Debuncher hits the target
  - 8 GeV protons
  - every 1695 ns / 200 ns width
- Production target
  - tungsten rod, 16 cm long with a 3 mm radius
  - produces pions that then decay to muons
- Solenoid
  - a graded magnetic field between 4.6 T (at end) and 2.5 T (towards the transport solenoid) traps the charged particles and accelerates them toward the transport solenoid

## • Transport Solenoid

- Graded magnetic from 2.5 T (at the entrance) to 2.0 T (at the exit)
  - Allows muons to travel on a helical path from the production solenoid to the detector solenoid
- S-shaped to remove the detector solenoid out of the line of sight from the production solenoid
  - No neutral particles produced in the production solenoid enter the detector solenoid, photons, neutrons

off-center central TS collimator and 90° bends passes low momentum negative muons and suppresses positive particle and high momentum negative particles.

# The Mu2e Beamline

- The **Detector Solenoid** houses the Al target and the two main detectors: the tracker and the calorimeter

- 17 Aluminum disks, 0.2 mm thick, radius between 83 mm (upstream) and 63 mm (downstream)

- Surrounded by graded magnetic field from 2.0 T (entrance) to 1.0 T (exit)
  - Conversion electrons will travel on a helical path toward the tracker and then hit the calorimeter
  - Electrons produced in the opposite direction from the tracker experience an increased magnetic field which reflects them back toward the tracker

Negative muons

# The Mu2e Tracker

## Detector requirements:

1. Small amount of budget material, maximizing  $X_0$
2.  $\sigma_p < 115 \text{ keV @ } 105 \text{ MeV}$
3. Good rate capability:
  - 20 kHz/cm<sup>2</sup> in live window
  - Beam flash of 3 MHz/cm<sup>2</sup>
4. dE/dx capability to distinguish  $e^-/p$
5. Operate in  $B = 1 \text{ T}$ ,  $10^{-4} \text{ Torr}$  vacuum
6. Maximize/minimize acceptance for CE/DIO

- dual ended TDC/ADC readout
- large Radii
- 5 mm diameter straw
- Spiral wound
- Walls: 12  $\mu\text{m}$  Mylar + 3  $\mu\text{m}$  epoxy + 200  $\text{\AA}$  Au + 500  $\text{\AA}$  Al
- 25  $\mu\text{m}$  Au-plated W sense wire
- 33 - 117 cm in length

- Self-supporting "panel" consists of 100 straws
- 6 panels assembled to make a "plane"
- 2 planes assembled to make a "station" -> 18 stations
- Rotation of panels and planes improves stereo information
- >20k straws total

# The Mu2e Tracker

- Inner 38 cm is purposefully un-instrumented
  - Blind to beam flash
  - Blind to >99% of DIO spectrum

# The Mu2e tracker

- Prototype panels complete, ramping-up production line
- Preparing to assemble planes
- Orders placed for final production
- FEE prototypes tested successfully

# Mu2e Tracker Performance

- Performance well within physics requirements 115 keV/c momentum resolution

# The Mu2e calorimeter

---

The calorimeter has to:

- Provide high  $e^-$  reconstruction efficiency for  $\mu$  rejection of 200
- Provide cluster-based additional seeding for track finding
- Provide online software trigger capability
- Stand the radiation environment of Mu2e
- Operate for 1 year w.o. interruption in DS w/o reducing performance

the calorimeter needs to fulfill the following

- Provide energy resolution  $\sigma_E/E$  of  $O(6 \%)$
- Provide timing resolution  $\sigma(t) < 200 \text{ ps}$
- Provide position resolution  $< 1 \text{ cm}$
- Provide almost full acceptance for CE signal @ 100 MeV
- Redundancy in FEE and photo-sensors

A crystal based disk calorimeter

# The Mu2e Calorimeter

High granularity crystal based homogeneous calorimeter with:

- 2 Disks (Annuli) geometry to optimize acceptance for spiraling electrons
- Crystals with high Light Yield for timing/energy resolution → **LY(photosensors) > 30 pe/MeV**
- **2 photo-sensors/preamps/crystal** for redundancy and reduce MTTF requirement → now set to 1 million hours/SIPM
- Fast signal for Pileup and Timing resolution →  **$\tau$  of emission < 40 ns + Fast preamps**
- **Fast WFD to disentangle signals in pileup**
- **Crystal dimension optimized** to stay inside DS envelope  
→ reduce number of photo-sensor, FEE, WFD (cost and bandwidth) while keeping pileup under control and position resolution < 1 cm.
- Crystals and sensors should work in 1 T B-field and in vacuum of  $10^{-4}$  Torr and:  
→ **Crystals survive TID of 90 krad and a neutron fluency of  $3 \times 10^{12} \text{ n/cm}^2$**   
→ **Photo-sensors survive 45 krad and a neutron fluency of  $1.2 \times 10^{12} \text{ n/cm}^2$**

# The Mu2e Calorimeter

The Calorimeter consists of two disks containing 674  $34 \times 34 \times 200 \text{ mm}^3$  un-doped CsI crystals each

- $R_{\text{inner}} = 374 \text{ mm}$ ,  $R_{\text{outer}} = 660 \text{ mm}$ , depth =  $10 X_0$  (200 mm)
- Disks separated by 75 cm, half helix length
- Each crystal is readout by two array UV extended SiPM's ( $14 \times 20 \text{ mm}^2$ ) maximizing light collection.  
PDE=30% @ CsI emission peak = 315 nm.  
GAIN  $\sim 10^6$
- TYVEK wrapping
- Analog FEE is onboard to the SiPM ( amplification and shaping) and digital electronics located in electronics crates (200 MhZ sampling)
- Cooling system - SiPM cooling, Electronic dissipation
- Radioactive source and laser system provide absolute calibration and monitoring capability

# The Mu2e Calorimeter

# Mu2e Pattern Recognition

- ❑ Search for tracking hits with time and azimuthal angle compatible with the calorimeter clusters (  $|\Delta T| < 50 \text{ ns}$  ) → simplification of pattern recognition
- ❑ Add search of an Helix passing through cluster and selected hits + use calorimeter time to calculate tracking Hit drift times

# Mu2e Pattern Recognition

Stopping Target

Straw Tracker

Crystal Calorimeter

A signal electron, together with all the other interactions

particles with hits within  $\pm 50$  ns of signal electron  $t_{\text{mean}}$

# Mu2e Pattern Recognition

- Cluster time and position are used for filtering the straw hits:
  - ✓ time window of  $\sim 80$  ns
  - ✓ spatial correlation

no selection

calorimeter selection

- black crosses = straw hits, red circle = calorimeter cluster,  
green line = CE track

# Module 0 and test beam - 2017

Large EMC prototype: 51 crystals, 102 SiPMs, 102 FEE boards

- Goals:
  - Test the performances
  - Test integration and assembly procedures
  - Test of temperature stability
  - Next: operate under vacuum, temperature and irradiation

► Cosmic equalization provide **energy res at the level of 5 %**

►  $\Delta T = t_{\text{SiPM1}} - t_{\text{SiPM2}} \quad \sigma_T \sim 130 \text{ ps} \quad @E_{\text{beam}} = 100 \text{ MeV}$

# Signal extraction and sensitivity

Expected background contributions and possible conversion signal in Mu2e

$$N_{\mu e} = 7.9$$

$$N_{\text{DIO}} = 0.14$$

$$N_{\text{Other}} = 0.27$$

X Design goal: single-event-sensitivity of  $3 \times 10^{-17}$

Requires  **$10^{18}$  stopped muons**  
 **$10^{20}$  protons on target**  
 high background suppression ( **$N_{\text{bckg}} < 0.5$** )

X Expected limit:  $R_{\mu e} < 2.5 \times 10^{-17}$  @ 90% CL

➤ Factor  $10^4$  improvement

X Discovery reach (5s):  $R_{\mu e} > 1.9 \times 10^{-16}$

➤ Covers broad range of new physics theories

# Summary

---

- Improves sensitivity by a factor of  $10^4$  SINDRUM II limit
  - Reach Sindrum-II sensitivity in 100 min
  - x10 in 17 hours running
  - x100 in 7 days running
  - x10000 in 700 days running
- Provides discovery capability over a wide range of NP
- is complementary to LHC, heavy-flavor, and neutrino experiments

## **Schedule:**

- Full scale solenoid construction started in 2017
- Full scale detector construction started in 2018
- Solenoid and detector installation in 2020-2021
- Initial commissioning in 2022
- First physics running in 2023

- spares

# CLFV searches history

**Current best limits:**

**MEG-2016**  
 $\text{BR}(\mu \rightarrow e\gamma) < 4.2 \times 10^{-13}$

**SINDRUM-1988**  
 $\text{BR}(\mu \rightarrow 3e) < 1 \times 10^{-12}$

**SINDRUM-II 2006**  
 $R_{\mu e} < 6.1 \times 10^{-13}$

**MU2E GOAL:**  
 $R_{\mu e} = 2.5 \times 10^{-17}$

# The Cosmic ray Veto

Cosmic  $\mu$  can generate background events via decay, scattering, or material interactions. Veto system covers entire DS and half TS

- Area: 327 m<sup>2</sup>
- 86 modules of 6 lengths
- 5,504 counters
- 11,008 fibers
- 19,840 SiPMs
- 310 Front-end Boards

- Will use 4 overlapping layers of extruded plastic scintillator
  - Each bar is 5 x 2 x ~450 cm<sup>3</sup>
  - 2 (1,4 mm  $\varnothing$ ) WLS fibers / bar
  - Read-out both ends of each fiber with 2 x 2 mm<sup>2</sup> SiPM
  - Have achieved  $\epsilon > 99.4\%$  (per layer) in test beam

$$\text{Normalization, } R = \frac{\Gamma(\mu Al \rightarrow e Al)}{\Gamma_{\text{capture}}(\mu Al)}$$

## Design of Stopping Target monitor

- High purity Germanium (HPGe) detector
  - Determines the muon capture rate on Al to about 10% level
  - Measures X and  $\gamma$  rays from Muonic Al
    - 347 keV 2p-1s X-ray (80% of  $\mu$  stops)
    - 844 keV  $\gamma$ -ray (4%)
    - 1809 keV eV  $\gamma$ -ray (30%)
- Downstream to the Detector Solenoid
- Line-of-sight view of Muon Stopping Target
- Sweeper magnet
  - Reduces charged bkg
  - Reduces radiation damage
